1.1 FALL3D results

FALL3D v7.0 (Folch *et al.*, 2014; <http://bsccase02.bsc.es/projects/fall3d/Downloads/fall3d-7.0.pdf>), was run using NCEP re-analysis data. The domain size is 80° longitude from 30° W to 50° E, and 60° latitude starting at 10° N to 70° N. The model
5 grid points are in 0.2° increments giving 401 x 301 total grid cells. There are 101 vertical layers in 100 m intervals up to 10 km. The total run time was varied up to 96 hours from initialisation. The particle granularity distribution was unimodal

with a diameter of $16\ \mu\text{m}$. Particle bulk density was $2500\ \text{kg m}^{-3}$. All particles were assumed to be spherical and particle (wet) aggregation, although available in the model, and break-up were not considered. Removal by gravitational settling/dry deposition are included. For the purposes of examining separation of gas and particles it was beyond the scope of this paper to provide more realistic particle habit. The vent is located at 17.33°W , 64.42°N , $1.74\ \text{km}$ (a.s.l.) and the source term used was

5 PLUME (see documentation for details) and a bi-Gaussian vertical distribution. The model solves for the mass flow rate and outputs the mass concentrations at each vertical level at every grid point. The column height for the results shown here was $3.731\ \text{km}$ (a.s.l.).

Many other model runs were done to look at sensitivity to various parameters but it is beyond the scope of this paper to discuss all the results. Here we present results that best model the satellite observations and we acknowledge that many

10 processes have been neglected or ignored entirely (e.g. particle habit).

Figure S1. Total ash column mass loading (g m^{-2}) determined from the volcanic ash transport model FALL3D using NCEP wind fields at 6-hourly intervals (except between 13:00–18:00 UTC), starting at; (a) 13:00 UTC, 22 May (b) 18:00 UTC, 22 May (c) 00:00 UTC, 23 May, (d) 06:00 UTC, 23 May, (e) 12:00 UTC, 23 May, and (f) 18:00 UTC, 23 May.

1.2 Satellite data retrievals

The satellite data used in our study is listed in Table 1. Some of the satellite retrievals are shown here and discussed in the main paper. AIRS was utilised to retrieve SO₂ slant column densities (SCDs) and also to investigate the effect of the dense ash column on the AIRS spectral brightness temperatures. OMI data were also used to retrieve SO₂ SCDs using ultra-violet light.

- 5 MODIS data at higher spatial resolution ($\sim 1 \text{ km}^2$) than either AIRS or OMI were used to retrieve ash mass loadings. Finally, SEVIRI data at decreased spatial resolution ($\sim 4\text{-}30 \text{ km}^2$) but high temporal resolution (15 minutes) were used to retrieve ash mass loadings and also to investigate the rapid plume rise (Figure 3) by analysing the single-channel cloud-top brightness temperatures.

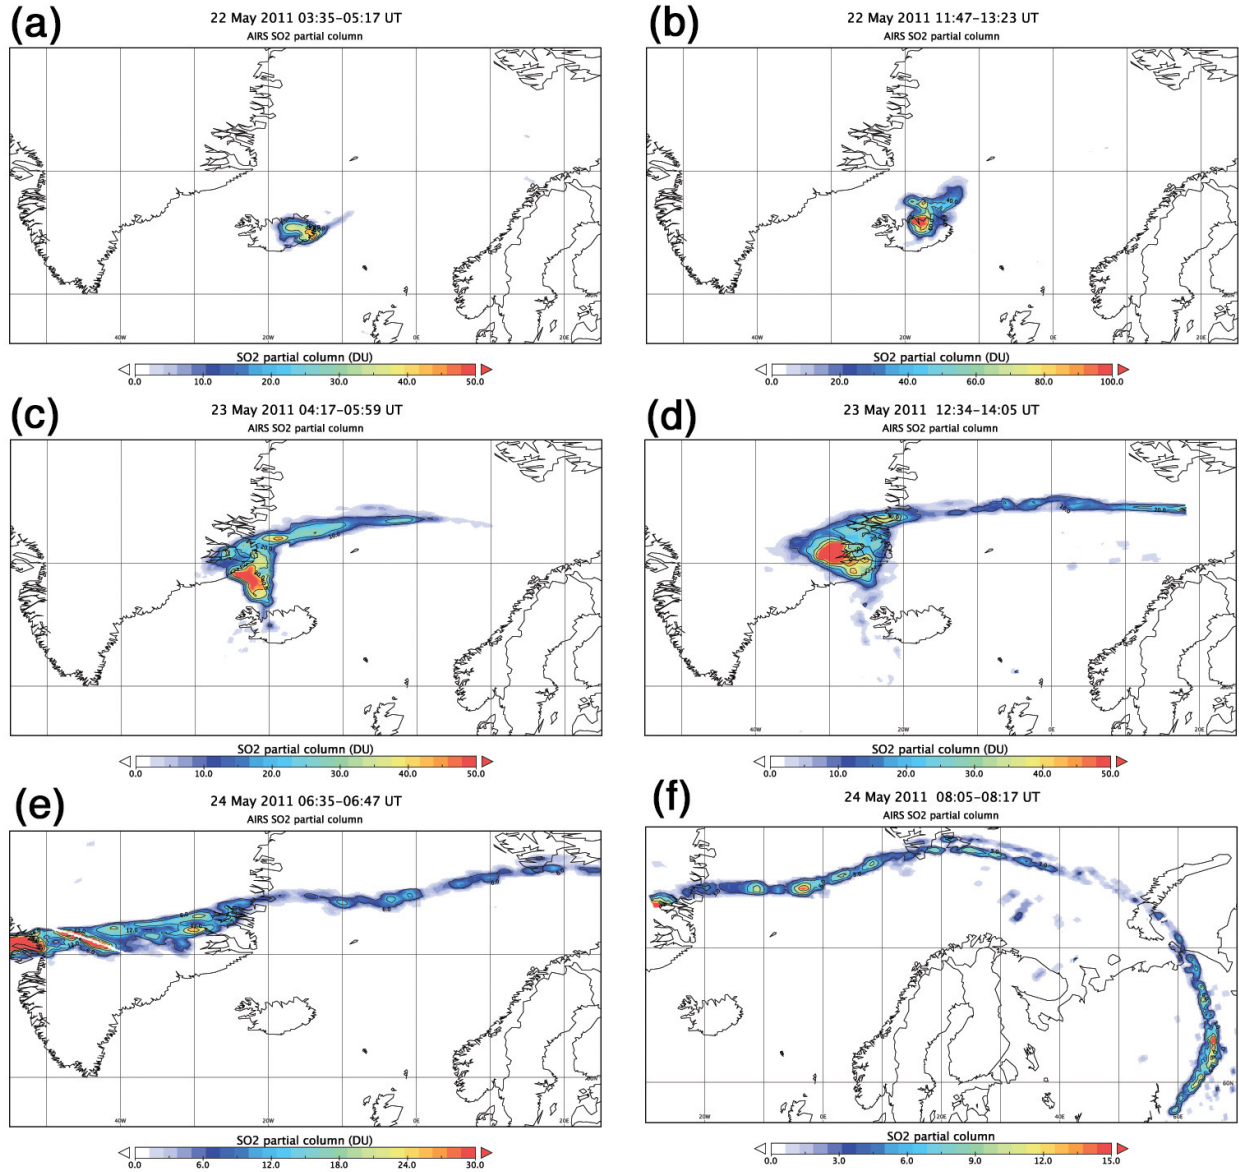

Figure S2. SO₂ retrievals from the AIRS sensor for 22–24 May 2011. Units are DU (Dobson Units; 1 DU $\approx 2.69 \times 10^{16}$ molecules cm⁻²). The AIRS detected SO₂ emissions travelling northwards and then spreading in a long filament eastwards and westwards. Each panel represents more than one granule (i.e. covering a specific time span): (a) 03:35–05:17 UT, 22 May, (b) 11:47–13:23 UT, 22 May, (c) 04:17–05:59 UT, 23 May, (d) 12:34–14:05 UT, 23 May, (e) 06:35–06:47 UT, 24 May, and (f) 08:05–08:17 UT, 24 May. A single AIRS granule corresponds to approximately 6 minutes. Note that AIRS is only sensitive to upper troposphere SO₂.

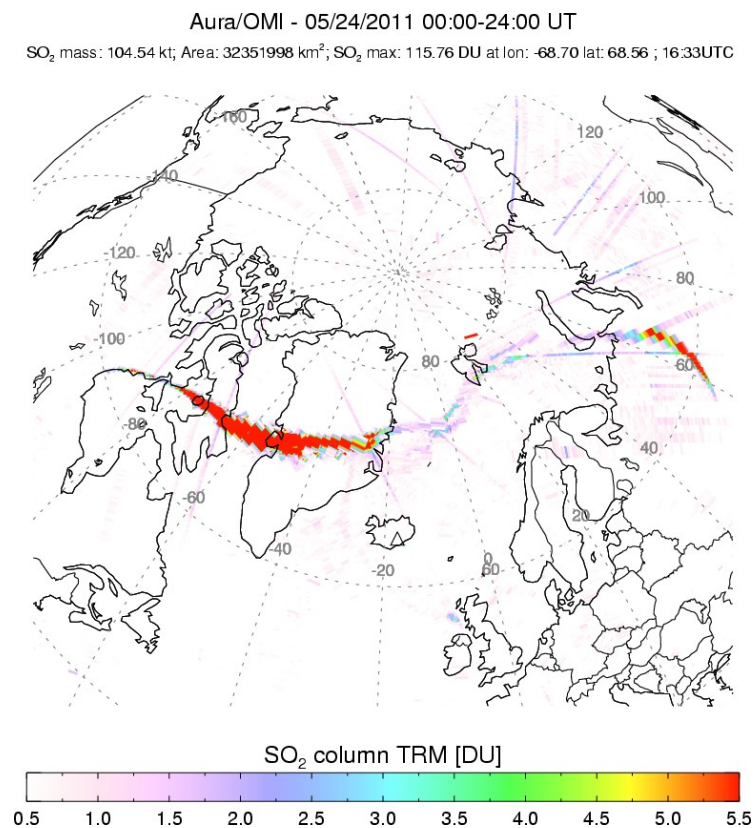

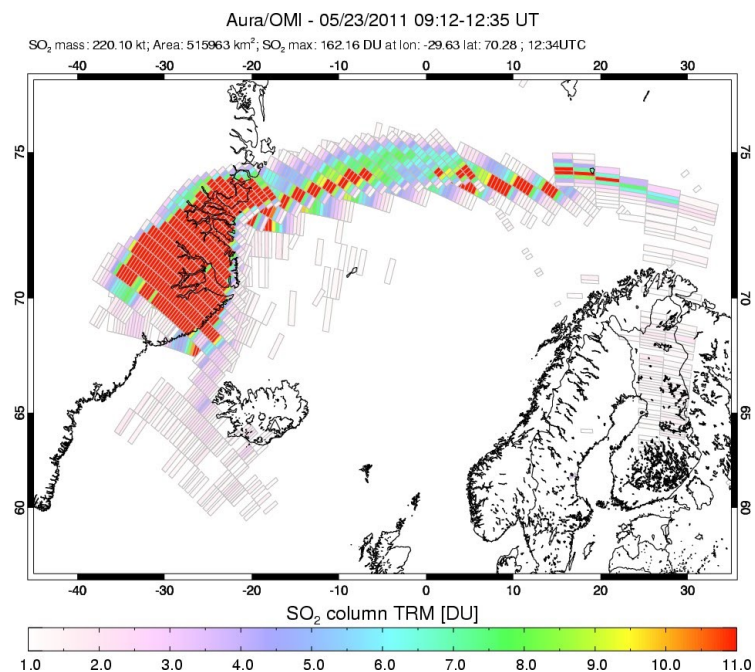

Figure S3. SO₂ retrievals from OMI on 23 and 24 May. Units are Dobson Units (DU). TRM stands for middle tropospheric SO₂ column with a centre of mass altitude of ~ 7.5 km.

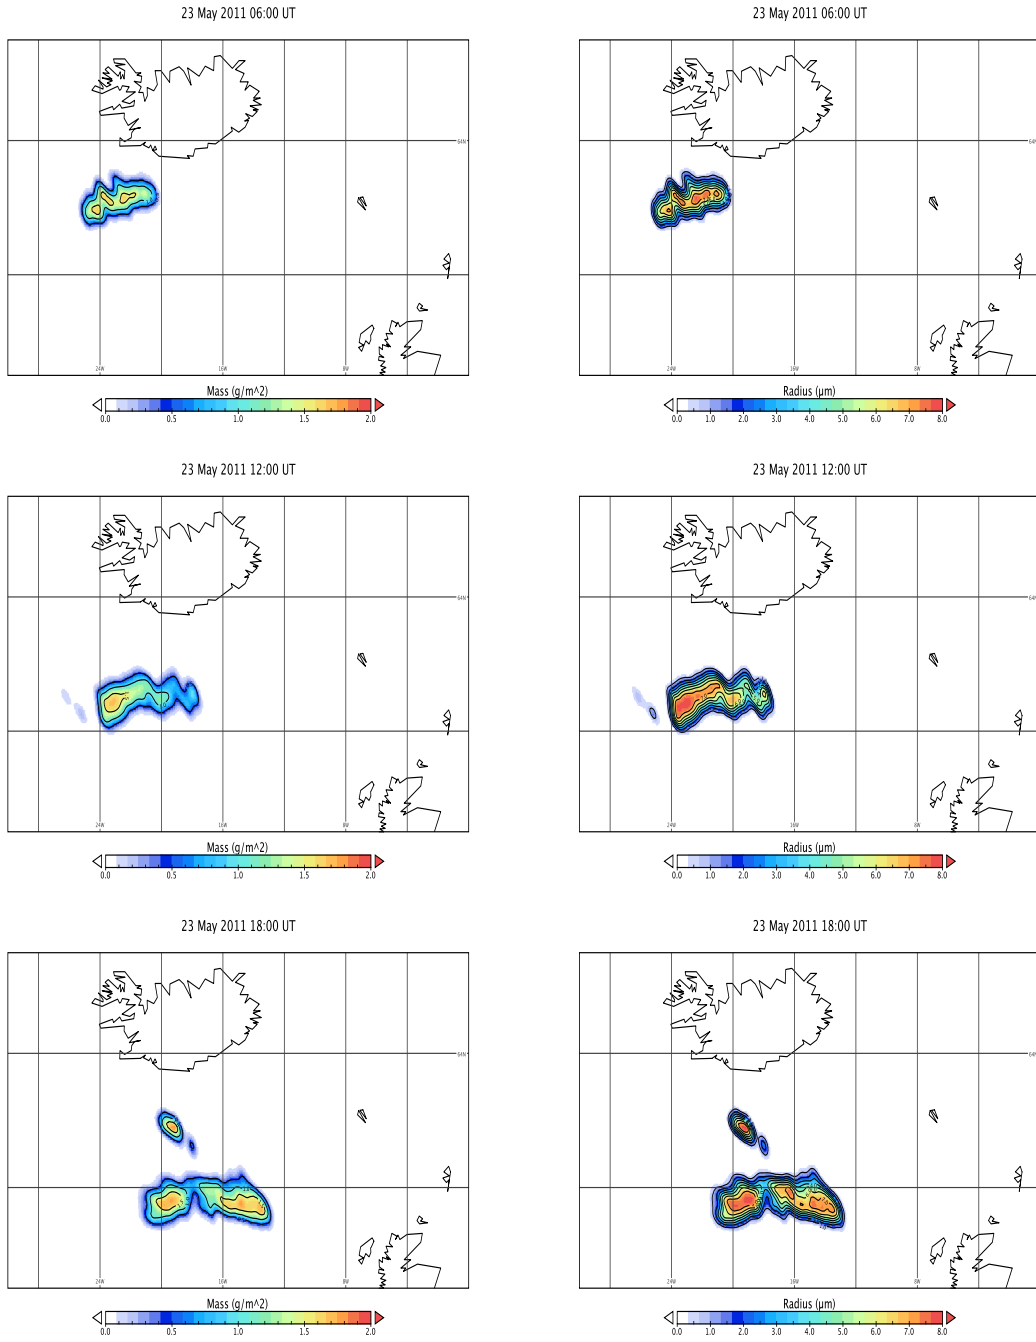

Figure S4. Ash retrievals from the SEVIRI instrument at 6 hour intervals on 23 May 2011. Left-hand panels: ash mass loadings in g m^{-2} . Right-hand panels: Effective particle radius (μm).

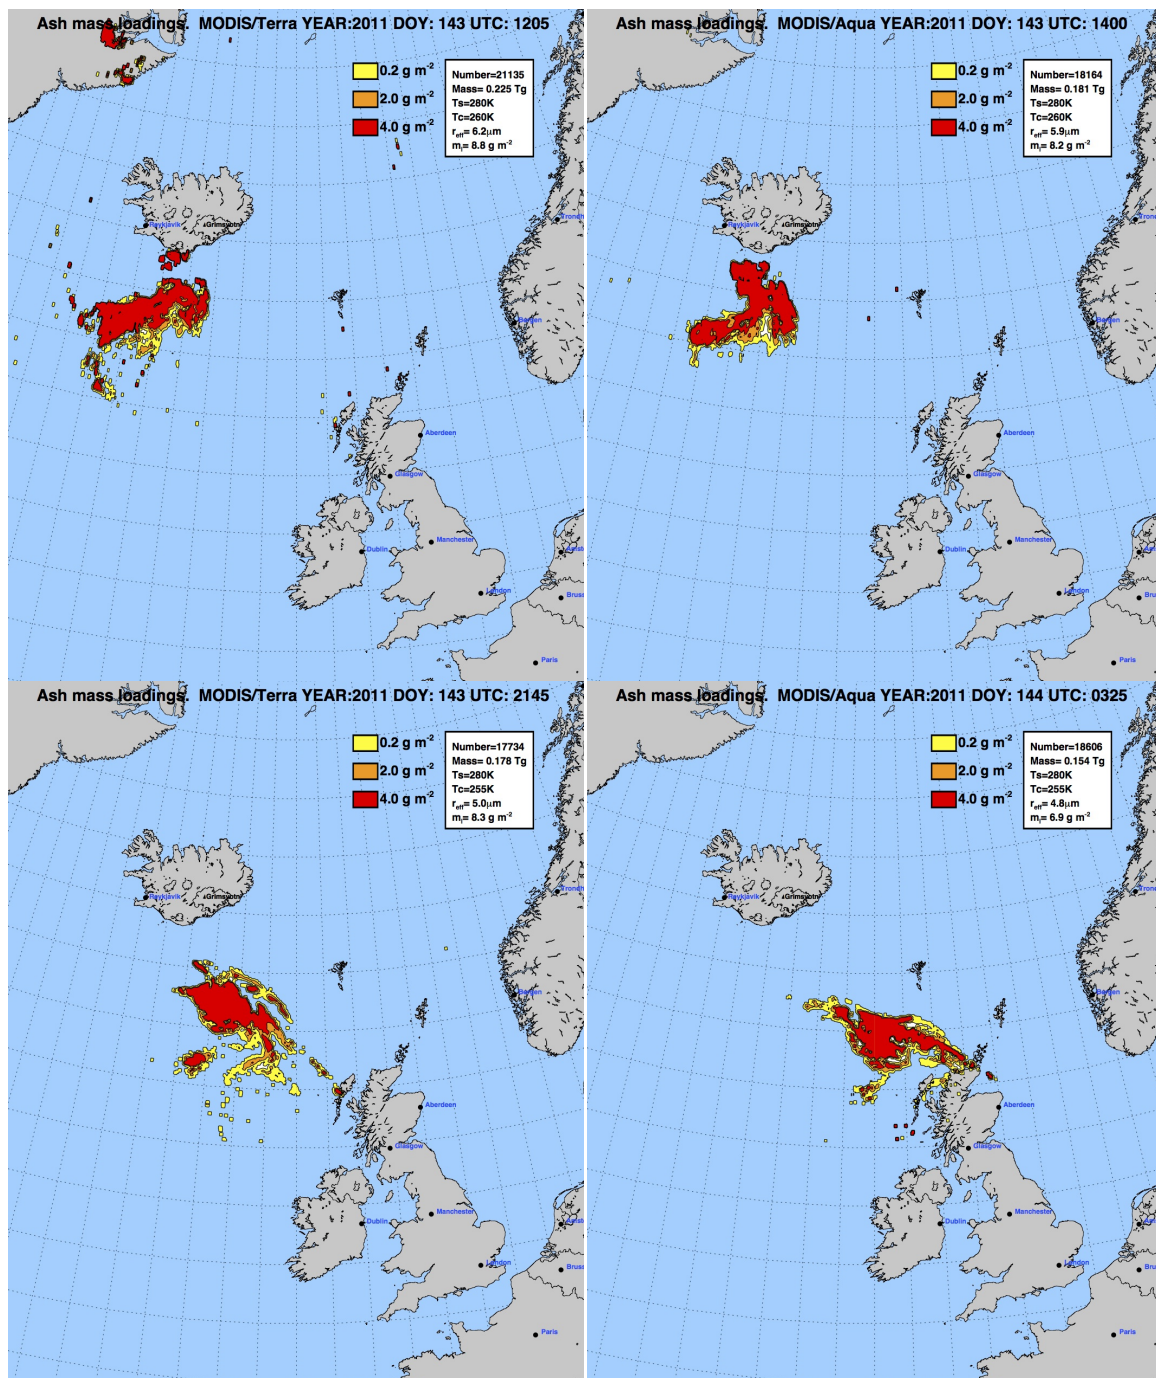

Figure S5. Ash mass loading retrievals using data from the MODIS Terra and Aqua sensors on 23 and 24 May, 2011. Information on the retrieved parameters, mean mass loading, mean effective particle radius, total mass, cloud top and surface temperature are provided in the panel inset on each map. Day 143 corresponds to 23 May.
